- Flash flooding in steep mountain catchments may result in the development and propagation of hyperconcentrated and debris flows
- These phenomena represent the most relevant natural hazards in mountain regions.
- In Europe, these flows cause extensive damages and casualties every year

Working Group F Thematic Workshop  
**FLASH FLOODS AND PLUVIAL FLOODING**

40° 26'

## Definition

- Rapid gravity-driven mass flows of water and sediment, with large solid concentrations such that their rheology is non-newtonian (i.e. non linear stress-strain relationship)

(Debris flood)

Flow	$C_v$ (%)	Density (g/cm <sup>3</sup> )
Water flood	0 - 20	1.0 - 1.33
Hyperc. flow	20 - 47	1.33 - 1.80
Debris flow	47 - 77	1.80 - 2.30

Caution ! Boundaries between types differ among authors !

## Monitoring stations

An invaluable  
contribution for the  
understanding of such  
processes

Moscardo Torrent  
Eastern Italian Alps

## How to cope with debris flow risk ?

- Structural measures → Reduce hazard
- Non-structural measures → Reduce vulnerability

Their combination is in most cases needed

Working Group F Thematic Workshop

FLASH FLOODS AND PLUVIAL FLOODING

## Structural measures

- Check-dams, retention basins, dikes, and artificial channels to stop, divert or “flush” debris flows
- Effective in most cases, but may present management problems (maintenance costs)

## Non-structural measures

- Reduce permanently (land use planning) or temporarily (warning systems) the probability that humans and their belongings might be hit by debris flows
- Permanent solutions are ideal, but socio-economic conflicts !
- Two types of warning systems:
  - “Advance” (early) warning systems predict the possible occurrence of a debris flow event by monitoring the possible onset of triggering conditions (rainfall threshold). ➡ Longer lead time, but low reliability
  - “Event” (alert) warning systems detect a debris flow when it already started its propagation. ➡ Reliable, but shorter time (few minutes) !

## A new study site for monitoring and testing warning systems in the Italian Alps

Basin area: 6 km<sup>2</sup>

Min elevation: 1,400 m a.s.l.

Max elevation: 2,930 m a.s.l.

Average annual precipitation: 500 mm

Working Group F Thematic

E DELLA TUTELA DEL TERRITORIO E DEL MARE

..but the open check-dam is not actually open !

- Each year the Province of Bolzano spends 200,000 € for sediment removal and disposal

## Objectives of the project

- Determine deposition patterns in the retention basin, in order to design improved filters of the check-dam
- Assess debris flow triggering and propagation dynamics (i.e. triggering conditions, flow velocity)
- Tests protocols of warning systems (to be applied in other basins), including the alert and evacuation stage (civil protection management)

## Main technical issues of the project

- The main technical problem in similar basins is the communication of remote instruments (not cable transmission possible)
- GSM-GPRS may work well, but in certain areas (as in the Gadoria) there is no coverage
- Radio transmission is then needed, but it suffers from certain limitations: range, power supply, costs
- Continuous instruments self-checks and redundancy is fundamental to guarantee reliable warning.
- Who is eventually responsible to issue the evacuation alert ? When ?  
We will test different protocols with Local Fire dept. and Civil protection

## Conclusions

- We still know little about debris flow processes ! We need to invest in long-term monitoring programme
- Combined use of structural and non-structural measures is often required. But need to achieve a positive cost-benefit balance.
- It is vital to map debris flow hazards also in presently unpopulated areas, because once urbanization starts, mitigation costs soar !!
